Colegio San Caio Book Software Manual

Language Selection, Release Configuration, and Deployment Guide

Colegio San Caio Publishing & Development Team

October 21, 2026

Abstract

This manual details the procedures for deploying, configuring, and executing the Colegio San Caio book software package. It provides precise instructions on selecting interface and publication languages via release assets, configuring local environments in Termux, and maintaining integrity through automated SHA-256 checksum verification.

1 System Architecture & Prerequisites

The Colegio San Caio book software framework is engineered to run seamlessly across local development nodes and automated CI/CD pipelines.

- **Environment:** Termux (Android emulation environment) with Git, GitHub CLI (`gh`), and core utilities.
- **Authentication:** HTTPS protocol integrated with GitHub CLI credentials (`gh auth setup-git`).
- **Verification Protocol:** SHA-256 checksum verification for all localized releases and repository assets.

2 Release Management and Asset Structure

Releases hosted under the Colegio San Caio organization namespace contain compiled book software binaries and localized manual templates. To retrieve and unpack a release asset:

```
# Clone the target repository or fetch release assets
gh release download v1.0 --repo Colegio-San-Caio/978-3-00-068463-0
sha256sum --check checksum.sha256
```

3 Language Selection Workflow

The software supports multi-language execution. Language parameters are declared upon initialization of the configuration file or via command-line arguments during release execution.

3.1 Supported Language Identifiers

3.2 Selecting Language via Configuration File

To permanently set your preferred language, open the software configuration file (`config.json`) located in the root release directory:

Language	Identifier	Configuration Flag
English (Default)	`en`	`-lang=en`
Spanish	`es`	`-lang=es`
Portuguese	`pt`	`-lang=pt`

Table 1: Supported Language Codes and Execution Flags

```
{
  "edition": "Colegio-San-Caio-Standard",
  "isbn": "978-3-00-068463-0",
  "language": "es",
  "verification": "sha256"
}
```

4 Automated Deployment and Repository Synchronization

For administrators maintaining portfolio repositories across the organization and personal namespaces (`clevjhon`), the automated pipeline script handles divergence and checksum generation:

```
#!/bin/bash
cd ~/oeneye/isbn_repo
git config pull.rebase false
git pull origin main --allow-unrelated-histories
sha256sum README.md > checksum.sha256
git add README.md checksum.sha256
git commit -m "Automated synchronization and checksum verification"
git push -u origin main
```

5 Verification and Troubleshooting

If merge conflicts arise due to concurrent updates on remote repositories, resolve them by prioritizing local workspace versions:

```
git checkout --ours README.md
git add README.md checksum.sha256
git commit -m "Resolve merge conflict with local preference"
```
